# Resting Membrane Potential

- Inside of neuron more **negative** relative to outside (-70mV).
- Achieved by:
  - Sodium-potassium pump – **active transport** (3 Na<sup>+</sup> **out** for 2 K<sup>+</sup> **in**).
  - Potassium (ungated) channels **opened**.

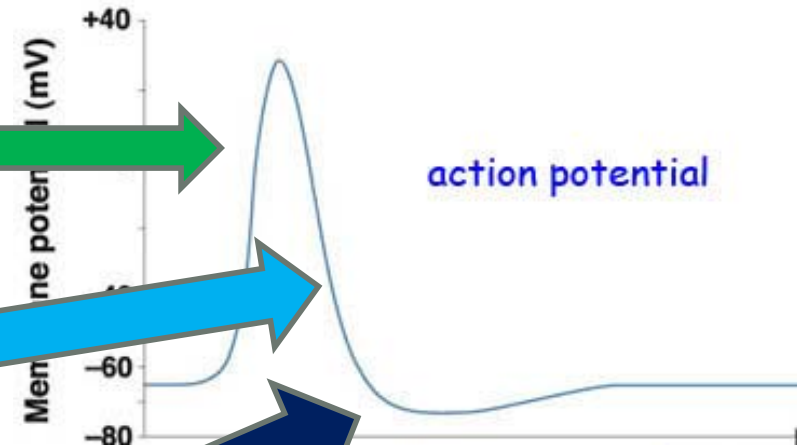

**A** A protein pump in the neuron cell membrane uses the energy of ATP to pump Na<sup>+</sup> out of the cell, and at the same time to pump K<sup>+</sup> in.

**B** The cell membrane is leakier to K<sup>+</sup> than it is to Na<sup>+</sup>. Because more positive charges leak out of the cell than leak in, the inside of the cell becomes negatively charged with respect to the outside.

# Effects of Various Stimuli

- **Depolarization**
  - **Inside more positive.**
- **Repolarization**
  - **Inside more negative.**
- **Hyperpolarization**
  - Inside **more negative** than resting

# Gated Ion Channels

- **Ligand-gated ion channels:**
  - **Found at dendrites and open/close when bound to neurotransmitters.**
- **Voltage-gated ion channels:**
  - **Found in axons.**
  - **Open/close when membrane potential changes.**

## How voltage-gated channels work

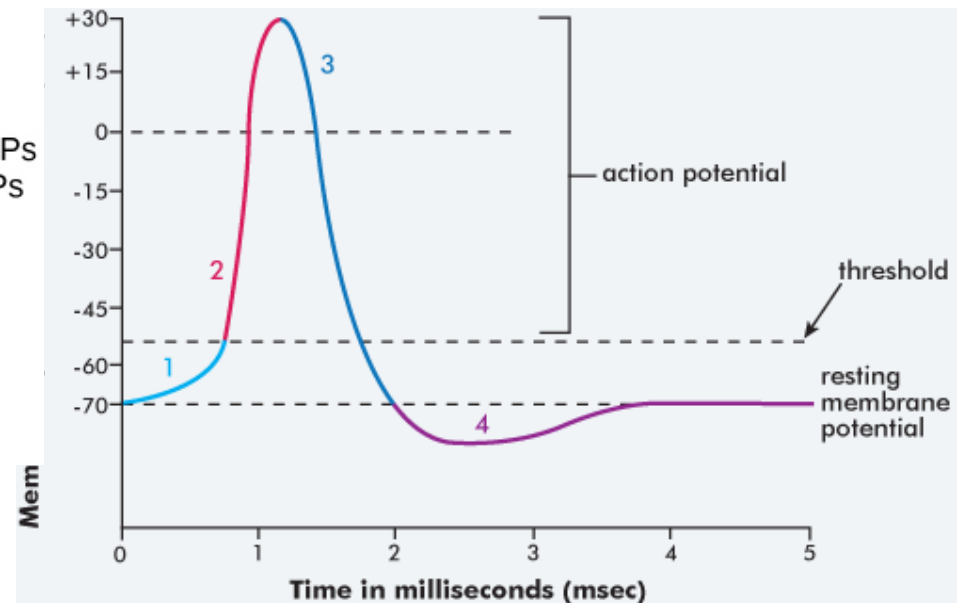

At the resting potential, voltage-gated Na<sup>+</sup> channels are closed.

When the membrane is depolarized, conformational changes open the voltage-gated channel.

# Action Potential (AP)

- A **moving depolarization**
- Triggered by a stimulus strong enough to produce a **depolarization to threshold**.

# Action Potential Generation

## 1. Resting State:

- **-70mV** within cell due to **sodium-potassium pumps**

- All voltage-gated channels inactive/closed

## 2. Excitation:

- Stimulus causes **Na<sup>+</sup> voltage-gated channels** to **open, Na<sup>+</sup> into cell**

- **Charge** difference **decreases**

- If threshold reached AP continues, if not back to resting state

### 3. Depolarization:

- **Na<sup>+</sup> influx** causes further depolarization, opening **more Na<sup>+</sup> voltage-gated** channels.

### 4. Repolarization:

- **Na<sup>+</sup> voltage-gated channels inactivating.**
- **K<sup>+</sup> voltage-gated channels open, K<sup>+</sup> flows out** of cell.

## 5. Undershoot:

- **K<sup>+</sup> voltage-gated channels open longer** than needed, creating an “undershoot”.
- **Na<sup>+</sup> channels** are in **resting** state
- Prevents a second stimulus from depolarizing membrane.
- This is known as the **relative refractory period**.
  - Limits the maximum frequency at which APs can be generated.
  - Ensures AP only moves in **one direction**

Leading edge of action potential

# Action Potential Generation

## Key:

- Resting membrane potential: Voltage-gated  $\text{Na}^+$  channels are in the resting state and voltage-gated  $\text{K}^+$  channels are closed
  - Stimulus causes depolarization to threshold
  - Voltage-gated  $\text{Na}^+$  channel activation gates are open
  - Voltage-gated  $\text{K}^+$  channels are open;  $\text{Na}^+$  channels are inactivating
  - Voltage-gated  $\text{K}^+$  channels are still open;  $\text{Na}^+$  channels are in the resting state
- Absolute refractory period
- Relative refractory period
